Aim: Write a python program to define a module and import a specific function in that module to another program

Python Modules

As our program grows bigger, it may contain many lines of code. Instead of putting everything in a single file, we can use modules to separate codes in separate files as per their functionality. This makes our code organized and easier to maintain.

Module is a file that contains code to perform a specific task. A module may contain variables, functions, classes etc. Let's see an example,

Let us create a module. Type the following and save it as example.py

```

bvs.py > add
1  def add(a, b):
2      result = a + b
3      return result
4  a = add(4, 5)
5  print(a)

Import Python Standard Library Modules

The Python standard library contains well over 200 modules. We can import a module according to our needs. Suppose we want to get the value of pi, first we import the math module and use math.pi. For example,

1  #import standard math module
2  import math
3  # use math.pi to get value of pi
4  print("The value of pi is", math.pi)

```

Python import with Renaming

In Python, we can also import a module by renaming it. For example,

import module by renaming it

```
bvs.py
1  import math as m
2  print(m.pi)

```

Python from...import statement

We can import specific names from a module without importing the module as a whole. For example,

import only pi from math module

```
bvs.py
1  from math import pi
2  print(pi)

Import all names

In Python, we can import all names(definitions) from a module using the following construct:

```
bvs.py
1  # import all names from the standard module math
2  from math import *
3  print("The value of pi is", pi)

```

The dir() built-in function

In Python, we can use the dir() function to list all the function names in a module.

We can use dir in math module in the following way:

```
bvs.py
1  import math
2  print(dir(math))
